## **METHOD AND APPARATUS FOR TREATING THE INSIDE SURFACE OF PLASTIC BOTTLES IN A PLASMA ENHANCED PROCESS**

The invention lies in the field of the packaging industry and relates to a method and an apparatus according to the generic parts of the corresponding independent claims, which method and apparatus serve for treating the inside surface of plastic bottles using a plasma enhanced process.

5

The term plastic bottle is used in the present description for a container made of a plastic material and having a body portion in the form of an upright cylinder with a circular or a non-circular cross section, a bottom portion on the one face of the body portion and a shoulder and neck portion with a relatively narrow opening on the other face of the body portion. Such containers are in particular bottles made e.g. of polyethyleneterephthalate (PET), polypropylene (PP) or high density polyethylene (HDPE), which bottles are e.g. produced by stretch blow moulding. Such bottles, for improving their gas barrier properties, are subjected to a coating treatment for coating their inner surface with a layer of silicon oxide in a plasma enhanced chemical vapour deposition process.

- 2 -

Other plasma enhanced processes used for treating the inside surface of plastic bottles are e.g. sterilizing processes or processes for activating or otherwise changing the surfaces.

5

Plasma enhanced processes for treating the inside surface of plastic bottles as well as devices for carrying out such processes have been described e.g. in the publications J. Weichart, B. Meyer, J. Müller (Vakuum in der Praxis Nr. 1, pages 22-26, 1991), US-5521351 (Wisconsin Alumni Research), JP-0853117 10 (Kirin Brewery), US-5378510 (Polar Materials Inc.), DE-3632748 (Vereinigung zur Förderung des Instituts für Kunststoffverarbeitung in Industrie und Handwerk an der TH Aachen) and WO-95/22413 (Coca-Cola Company).

15 A plasma enhanced process for treating the inside of a bottle generally comprises the steps of reducing the pressure within the bottle, igniting and sustaining a plasma within the bottle by activating a suitable power source (DC, RF, HF, microwave) and flowing a suitable process gas or process gas mixture through the plasma. In most cases it is necessary to evacuate the 20 room outside of the bottle also in order to prevent the bottle from collapsing. Advantageously the room outside the bottle is evacuated to a pressure which is approximately ten times lower than the pressure inside the bottle such preventing ignition of a plasma on the outside of the bottle.

25

Devices for carrying out such processes therefore comprise: a vacuum chamber, in which the bottle to be treated is positioned, means for evacuating the vacuum chamber and means for evacuating the inside of the bottle (usually two different reduced pressures), means for igniting and sustaining a 30 plasma (e.g. generator for RF- or HF-frequency or microwave generator) and means for feeding the process gas into the bottle.

It is the object of the invention to provide a method and an apparatus for treating the inside surface of plastic bottles in a plasma enhanced process, e.g. plasma enhanced chemical vapour deposition of a silicon oxide coating. Using 5 the inventive method and apparatus is to make it possible to produce a high quality product in an economically feasible process and the inventive apparatus is to be easily upscaleable for a high capacity process.

10 This object is achieved by the method and apparatus as defined by the claims.

The inventive apparatus comprises a vacuum chamber and a substantially cylindrical microwave confinement to which microwaves generated by a 15 microwave generator are coupled through one of the faces with the aid of suitable coupling means, whereby the function of the microwave confinement and of the vacuum chamber may be taken over partially or fully by the same apparatus part. It further comprises evacuation means and gas feed means. The microwave confinement is adapted to the shape of at least the body 20 portion of the bottle as closely as possible. The microwave confinement, the coupling means and the microwave generator are designed and tuned such that the microwave confinement is excited in a TM resonance mode, i.e. by a transverse magnetic wave, in which the magnetic field does not have axial components. In addition a permanent magnetic field can be generated by 25 providing stationary magnets which magnetic field is preferably such that within the bottle to be treated electron cyclotron resonance conditions are achieved.

30 The inventive apparatus is very compact and very simple. For upscaling, a plurality of one-bottle apparatuses is arranged in a row or in a matrix and all

- 4 -

the one-bottle apparatuses are connected to a net of energy, vacuum and gas supply lines. Each of the one-bottle apparatuses may have its own vacuum chamber or the plurality of microwave confinements may be arranged in one common vacuum chamber.

5

Exemplified embodiments of the inventive apparatus are described in connection with the following Figures. Wherein:

10 **Figures 1 and 2** show the principle of an exemplified embodiment of the inventive apparatus for treating one bottle at a time in an operative or closed configuration (Figure 1) and in an open configuration (Figure 2);

15 **Figure 3** shows a further embodiment of the inventive apparatus integrated in a stretch-blow-moulding apparatus, in which apparatus a bottle is stretch-blow-moulded and immediately afterwards is treated in a plasma enhanced process;

20 **Figure 4** shows a further embodiment of the inventive apparatus integrated in a filling apparatus, in which apparatus the bottle is filled immediately after treatment in the plasma enhanced process;

25 **Figures 5 and 6** show schematic exemplified embodiments of the inventive apparatus for simultaneous treatment of a plurality of bottles in a plasma enhanced process;

**Figure 7** shows a three dimensional representation of an embodiment of the inventive apparatus according to Figure 5;

30

**Figure 8** shows schematically a further exemplified apparatus for plasma treating batches of bottles in an array of inventive one-bottle-apparatuses.

5

**Figures 1 and 2** show an exemplified embodiment of the inventive apparatus for treating one bottle 1 at a time. The apparatus comprises a vacuum chamber 2 and a cylindrical microwave confinement 3 or part of a microwave confinement within the vacuum chamber and wherein the bottle 1 to be treated is positionable. It further comprises a microwave generator 4 and suitable coupling means (10/11) for exciting the microwave confinement and a gas feed tube 5 reaching through the bottle opening into the inside of the bottle and consisting of a porous or perforated material. Figure 1 shows the apparatus in its operational or closed configuration, wherein the microwave confinement and the vacuum chamber are closed. Figure 2 shows the apparatus in its open configuration which open configuration serves for exchanging a treated bottle with a further bottle to be treated.

10 The microwave confinement 3 either consists of a material which is not transparent to microwave but allows pressure equilibration between its inside and its outside (e.g. is made of a perforated metal sheet) and is positioned within the vacuum chamber 2 or it is not transparent to micro waves and vacuum tight, i.e it takes over the function of the vacuum chamber at the 15 same time. In the embodiment according to Figures 1 and 2 the microwave confinement 3 comprises a perforated cylindrical part 3.1 which corresponds as closely as possible to the cylindrical body portion of the bottle 1. The cylindrical part 3.1 is closed on one side by a neck plate 3.2 which neck plate forms a wall part of the vacuum chamber 2 also and comprises means for holding the neck portion of the bottle 1 to be treated and means for sealing the inside of the bottle from the outside and carries the gas feed tube 5. The 20 25 30

- 6 -

neck plate also comprises means for connecting the gas feed tube to a process gas G source, means for connecting the bottle opening to a vacuum V.1 source and means for connecting the vacuum chamber to a vacuum V.2 source.

5

At the face 3.3 opposite the neck plate 3.2 and facing the bottom part of the bottle to be treated microwaves generated by a microwave generator 14 are coupled into the microwave confinement, e.g. via a hollow wave guide 11 through a microwave transparent window 10 which at the same time represents the vacuum chamber wall. The window 10 is e.g. made from quartz glass or plastic.

10 15 It is possible also, to use a vacuum chamber transparent to microwaves (from quartz or plastic) and to arrange it fully or partly within the microwave confinement.

20 25 The microwave generator 4, the microwave confinement 3 and the microwave coupling means are designed and tuned for a TM mode of resonance, preferably for a  $TM_{01n}$  mode wherein  $n$  is between 1 and 4. In the publications US-5311103 and US-4777336 devices showing such resonance are described.

For creating a stationary magnetic field inside the bottle 1 to be treated, the gas feed tube 5 may be equipped with a plurality of stationary magnets positioned either inside the tube or arranged on its outside. The gas feed tube 30 may further comprise cooling means for cooling the gas feed tube and the

- 7 -

magnets and keeping them at a temperature which is constant within narrow limits.

5 The gas feed tube may also be designed as a simple perforated tube or may be reduced to a gas feed nozzle positionable in the neck of the bottle to be treated.

10 For positioning a bottle 1 to be treated in the microwave confinement 3 (refer to Figure 2), the neck plate 3.2 is removed from the cylindrical part 3.1 of the microwave confinement 3. The means for holding the bottle neck are opened. Then the bottle 1 is positioned over the gas feed tube 5 or gas feed nozzle and is secured by the neck holding means. Then the bottle is introduced into 15 the vacuum chamber 2 and the microwave compartment 3 by moving the neck plate 3.2 towards the cylindrical part 3.1 until it forms a tight seal not only with the other wall parts of the vacuum chamber but also with the cylindrical part 3.1 of the microwave confinement.

20

Figure 3 shows a further exemplified embodiment of the inventive apparatus for coating one bottle 1 at a time. The apparatus is fully integrated into an apparatus for stretch-blow-moulding the bottle 1. The function of the vacuum chamber and of the microwave confinement are taken over by the cavity of 25 the blow mould 20. For the new functions the blow mould comprises a microwave window 10, e.g. made of quartz glass to which window 10 microwaves generated by the microwave generator 4 are coupled via the wave guide 11, and at least one channel 21 through which the mould cavity can be evacuated (V.2).

The stretching rod 22 of the stretch-blow-moulding apparatus is moved to its various positions by a linear motor 23. It is hollow and made of a porous or perforated material and serves as gas feed tube 5 in the plasma enhanced process. Therefore it comprises a connection to a process gas source G.

5

The apparatus according to Figure 3 is operated as follows:

- A preheated bottle preform 30 (in broken lines) is positioned in the cavity of the mould 20. The stretching rod/gas feed tube 22/5 is in an initial position its distal end being positioned against the bottom part of the preform. The vacuum connections of the mould are closed.
- Pressure P is applied to the inside of the preform and the stretching rod/gas feed tube 22/5 is advanced until it reaches or nearly reaches the bottom part of the mold opposite the bottle opening, such stretching the preform to approximately the axial length of the bottle to be produced.
- The pressure P is then increased for blowing the preform wall and pressing it onto the inside of the mould 20.
- The stretching rod/gas feed tube 22/5 is then brought into a gas feed position (distal end at a distance from the bottle bottom) and the inside of the bottle is evacuated simultaneously with the cavity of the mould, whereby the reduced pressure inside the bottle is suitable for igniting a plasma and the reduced pressure outside of the bottle is preferably too high or too low for igniting or sustaining a plasma but suitable to keep the bottle from collapsing.
- 30 - The microwave generator is activated and the process gas is fed to the stretching rod/gas feed tube 22/5 and is simultaneously removed through

the opening of the bottle (V.1) thereby maintaining a suitable process pressure.

- After the predetermined process time, the microwave generator and the process gas are stopped and the bottle 1 and the mould cavity are vented.
- The mould 20 is opened and the stretch-blow-moulded and treated bottle is removed from the mould.

10

Figure 4 shows a further exemplified embodiment of the inventive apparatus for treating one bottle 1 at a time. The apparatus corresponds substantially to the apparatus according to Figures 1 and 2. The function of the microwave confinement 3 is here taken over by the vacuum chamber 2. The apparatus further comprises means (not shown) for moving the gas feed tube 5 into a position outside of the bottle 1 (shown in broken lines (5)) and a connection in the neck plate 3.2 to a source of a liquid C to be filled into the treated bottle.

20

The apparatus according to Figure 4 is operated as follows:

- A bottle 1 is positioned in the microwave confinement/vacuum chamber. The gas feed tube 5 is brought into a gas feed position inside the bottle (distal end at a distance from the bottle bottom).
- The inside of the bottle 1 is evacuated simultaneously with the vacuum chamber 2, whereby the reduced pressure inside the bottle is suitable for igniting a plasma and the reduced pressure outside of the bottle is preferably too high or too low for igniting or sustaining a plasma but suitable to keep the bottle from collapsing.

- 10 -

- The microwave generator is activated and the process gas is fed to the gas feed tube 5 and is simultaneously removed through the opening of the bottle (V.1) thereby maintaining a suitable process pressure.
- 5 - After the predetermined process time, the microwave generator and the process gas are stopped.
- If necessary, the bottle is rinsed with a rinsing gas keeping a reduced pressure.
- 10 - The connection to the source of liquid content C is opened and the bottle is filled with the liquid sucked into the bottle due to the vacuum.
- The treated and filled bottle is sealed and removed from the microwave confinement/vacuum chamber.
- 15

The advantage of the apparatus according to Figure 4 is not only the use of the vacuum for filling the bottle but also the filling of the bottle straight after 20 the plasma treatment which renders the inside surface of the bottle not only e.g. coated but sterile also. Therefore, the use of an apparatus according to Figure 4 makes a sterilizing apparatus or means for sterile transport of the treated bottles to a filling apparatus unnecessary.

25

It is also possible to combine the features of the apparatus according to Figure 3 with the features of the apparatus according to Figure 4 resulting in a stretch-blow-moulding/plasma-treating/filling apparatus combined in one and the same apparatus.

30

- 11 -

Figures 5 and 6 show very schematic, exemplified systems for treating a plurality of bottles at one time. The basic idea of these systems is to provide a plurality of units 50, 51, 52... which substantially correspond to the apparatuses according to Figures 1 and 2 or according to Figure 4, whereby 5 the units may be arranged within a common vacuum chamber (Figure 5) or may each comprise its own individual vacuum chamber (Figure 6).

10 Each unit 50, 51, 52... is connected to a net of vacuum lines 55 for evacuating the bottles and to a net of gas feed lines 56 for the process gas and if applicable to a net of vacuum lines 57 for evacuating the individual vacuum chambers and to supply lines for a liquid content to be filled into the bottles.

15 The units in the systems according to Figures 5 and 6 are arranged in a row or in a matrix and are advantageously opened and closed using one common drive. A plurality of units can also form a line or rotary system of units wherein the units are moved either continuously or by increment.

20

Figure 7 shows with a bit more detail a system 70 according to Figure 5, i.e. a system with a row of twelve units 50 to 61 according to Figures 1 and 2 arranged in a row in a common vacuum chamber 71.

25

The bottles to be treated are supplied to the system by a supplying conveyor 72 and a branch conveyor 73 and are arranged in a bottle row 74 parallel to the row of units. The row of bottles may be positioned in a vacuum lock chamber. For positioning the bottles of the bottle row 74 into the units 50 to 30 61 the vacuum chamber is opened and the bottles are gripped by a gripper row 75. They are tilted and moved above the gas feed tubes 5 which are in a

position beneath the common neck plate 76. Then the gas feed tubes are raised and the vacuum chamber is closed. The bottles are then treated and after treatment are removed by opening the vacuum chamber, lowering the gas feed tubes, and tilting the bottles onto a removal conveyor 77.

5

Figure 8 shows a further exemplified apparatus for plasma treating batches of bottles in an array of inventive one-bottle-apparatuses. This array of one-bottle-apparatuses comprises a plurality of microwave confinements 3 each equipped as described with a microwave generator 4 and suitable coupling means 10/11, the microwave confinements being positioned in a common vacuum chamber 2 with a vacuum pump V.2 as described in connection with Figure 5, whereby microwave confinements 3 and vacuum chamber 2 are closed by a neck plate 82. The array further comprises an arrangement 80 comprising a plenum 81 connected to a vacuum pump V.1 and having openings aligned with the axes of each microwave confinement 3 and being tightly connectable to bottle openings or corresponding openings in the neck plate 82 and an array of gas feed means 5 also aligned with the axes of the microwave confinements and connectable to a source of process gas G.

10  
15  
20

Figure 8 shows from the left to the right three stages of a batchwise plasma treatment of bottles 1. Firstly (left side of the Figure), the batch of bottles is positioned on the neck plate 82, their axes aligned with the openings and the bottlenecks are fixed with suitable fixing means. Then (middle of the Figure), the neck plate 82 with the bottles 1 is positioned between the array of microwave confinements and the arrangement 80. Then (right side of the Figure) the neck plate 82 is raised for positioning the bottles 1 in the microwave confinements 3 and for closing the confinements 3 and the vacuum chamber 2. The arrangement 80 is also raised for positioning the gas feed

30

tubes 5 in the bottles 1 and for connecting the openings of the plenum 81 with the bottle openings or with the openings in the neck plate 82.

- 5 Instead of using a vacuum chamber 2 containing the microwave confinements only and venting it for each change of batch or bottles, it is possible to use a larger vacuum chamber containing also the arrangement 80 and moving the neck plate with the bottles into the vacuum chamber and out of it via a vacuum lock, i.e. positioning the neck plate with the bottles into a prechamber
- 10 connected to the vacuum chamber with a vacuum tight entrance door, evacuating the prechamber, opening the entrance door and moving the neck plate into the vacuum chamber. For removing the bottles after treatment, the vacuum chamber comprises an exit door and an evacuated after chamber, which afterchamber is vented for removing the neck plate with the treated
- 15 bottles. The advantage of such an arrangement is the fact that the vacuum chamber does not need venting on batch change and that for this reason shorter cycle times will be achieved.
- 20 In all examples described above, the plasma treatment is a one step process being carried out using one process gas or one mixture of process gases. In the same way though, plasma processes comprising a plurality of steps can be carried out also. The only apparatus adaptation necessary for such a process is means for corresponding switching of the connection of the process gas feed
- 25 means from a source of a first process gas to a source of a further process gas.

As already mentioned, one example of a plasma process for treating the inside surface of a bottle is coating this inside surface with an  $\text{SiO}_x$  layer for improving the gas barrier properties of the bottle. Such deposition on a 500ml PET bottle as available on the market carried out in an apparatus as

described above using the following process parameters gives the following results:

- process pressure inside bottle 0.2 mbar
- 5 - process pressure outside bottle 0.01 mbar
- flow of hexamethyldisiloxane 2 sccm
- flow of oxygen 16 sccm
- applied microwave power 150 W
- process time 12 s
- 10 - Oxygen permeation of treated bottle in comparison with untreated bottle (permeation measured on standard MOCON equipment):
  - uncoated bottle 0.050 0.0025 ccO<sub>2</sub>/bottle/day/0.21atm
  - coated bottle 0.006 0.0025 ccO<sub>2</sub>/bottle/day/0.21atm
- 15 This result represents an improvement in oxygen permeation by a factor of more than eight.

20 All modifications, alterations and changes coming within the spirit and scope of the invention as set forth in the appended claims are herein meant to be included.

## C L A I M S

5

1. Method for treating in a plasma enhanced process, the inside surface of a plastic bottle (1) having a substantially cylindrical body, a bottom portion on the one face of the body and a shoulder and neck portion with a relatively narrow opening on the other face of the body, the process comprising the steps of simultaneously evacuating the inside of the bottle (1) and the room outside of the bottle, igniting and sustaining a plasma inside the bottle and flowing a process gas (G) through the bottle for a predetermined process time and simultaneously venting the inside and the outside of the bottle after the predetermined process time, characterized in that for carrying out the process steps the bottle (1) is positioned substantially coaxially in a substantially cylindrical microwave confinement (3) whereby for igniting and sustaining the plasma inside the bottle (1), microwaves are coupled to the microwave confinement (3) from the one face of the confinement towards which the bottom portion of the bottle (1) is facing and whereby the microwave confinement (3) is excited in a TM mode of resonance.  
10
2. Method according to claim 1, characterized in that the TM mode of resonance is a  $TM_{01n}$  mode wherein n is one of 1, 2, 3 or 4.  
15
3. Method according to one of claims 1 or 2, characterized in that the bottle (1) is stretch-blow-moulded in a blow mould (20) with the help of a stretching rod (22) and in that the bottle is treated in the plasma enhanced process immediately after stretch-blow-moulding whereby the  
20

blow mould (20) is evacuated and microwaves are coupled into the blow mould (20) through a microwave window (10) in the face of the mould (20) and whereby the process gas (G) is fed into the bottle through the stretching rod (22) serving as gas feed tube (5).

5

4. Method according to claim 3, characterized in that the stretching rod/gas feed tube (22/5) is positioned into a gas feed position for the plasma enhanced process in which position its distal end is at a distance from the bottom of the bottle (1).  
10
5. Method according to one of claims 1 to 4, characterized in that the bottle (1) is filled immediately after treatment in the plasma enhanced process  
15 whereby instead of venting the inside of the bottle, a liquid (C) is sucked into the bottle.
6. Method according to one of claims 1 to 5, characterized in that the plasma enhanced process is a one step or a multistep process whereby in one of the steps the inside surface of the plastic bottle is coated with a layer of  $\text{SiO}_x$  for improving the gas barrier properties of the bottle.  
20
7. Plastic bottle made in a process according to claim 6, characterized in that the oxygen permeation of the coated bottle is improved by a factor of approximately eight compared with the bottle in its uncoated state.  
25
8. Apparatus for carrying out the method according to one of claims 1 to 6, the apparatus comprising a vacuum chamber (2), means for evacuating  
30

the vacuum chamber and the inside of a bottle (1) positioned in the vacuum chamber (2), means for igniting and sustaining a plasma inside the bottle and means for feeding a process gas (G) into the bottle, characterized in that the apparatus further comprises a substantially cylindrical microwave confinement (3) into which confinement the bottle is positionable substantially coaxially and in that it further comprises a microwave generator (4) and means for coupling the microwaves generated by the microwave generator (4) to the microwave confinement (3) from the one face towards which the bottom portion of the bottle is facing, whereby the microwave generator (4), the microwave coupling means and the microwave confinement (3) are designed and tuned for excitement of the microwave confinement in a TM mode.

15 9. Apparatus according to claim 8, characterized in that the means for feeding a process gas into the bottle (1) is a gas feed tube (5) positionable in the bottle (1) or a gas feed nozzle positionable in the opening of the bottle.

20

10. Apparatus according to claim 8 or 9, characterized in that the means for coupling the microwaves to the microwave confinement (3) comprises a microwave window (10).

25

11. Apparatus according to claim 10, characterized in that the microwave confinement (3) is defined by a cylindrical part 3.1 inside the vacuum chamber (2) and by a neck plate (3.2) and an opposite plate (3.3), the two plates (3.2 and 3.3) being parts of the vacuum chamber (2) and in that the opposite plate (3.3) comprises the window (10) which is transparent to microwaves.

12. Apparatus according to one of claims 8 to 11, characterized in that the microwave confinement (3) and the vacuum chamber (3) are the cavity of a blow mould (20) of a stretch-blow-moulding apparatus which mould (20) further comprises at least one channel (21) connectable to a vacuum source and a window (10) transparent for microwaves in the area of the bottom portion, and in that a stretching rod (22/5) of the stretch-blow-moulding apparatus is designed as hollow and perforated gas feed tube being connectable to a process gas (G) source.

10

13. Apparatus according to one of claims 8 to 11, characterized in that the gas feed tube (5) is removable from the bottle (1) and that the bottle opening is connectable to a source of a liquid (C) to be filled into the bottle (1).

15

14. Apparatus according to one of claims 8 to 13, characterized in that it is positioned within a line or matrix of similar apparatuses (50 to 61) which apparatuses are connected to the same vacuum sources (55, 57) and gas source (56).

20

15. Apparatus according to claim 14, characterized in that the matrix or line comprises a common vacuum chamber 71, in which the plurality of apparatuses is accommodated.

25

16. Apparatus according to one of claims 14 to 15, characterized in that the matrix or line comprises a vacuum plenum (81) extending over the whole

30

area of the matrix or line and connected to a vacuum pump to which vacuum plenum (81) all necks of bottles to be treated are connectable.

- 5      17. Use of the apparatus according to one of claims 8 to 16 in a production line following a stretch-blow-moulding apparatus.
- 10      18. Use of the apparatus according to one of claims 8 to 16 in a production line preceding a filling apparatus.

# INTERNATIONAL SEARCH REPORT

International Application No  
PCT/IB 98/01506

**A. CLASSIFICATION OF SUBJECT MATTER**  
IPC 6 H01J37/32 C23C16/04

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)  
IPC 6 H01J C23C B05D B29C B65D

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the International search (name of data base and, where practical, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	<p>WEICHART J ET AL: "Beschichtung von dreidimensionalen Substraten mit einem magnetfeldunterstützten Mikrowellen-Plasma bei Raumtemperatur." VAKUUM IN DER PRAXIS, vol. 3, no. 1, February 1991, pages 22-26, XP002067698 WEINHEIM DE cited in the application see page 24, left-hand column, last paragraph - page 25, left-hand column, last line; figures 2,3</p> <p>---</p>	1,2,8
Y	<p>DE 196 00 223 A (ASCHERMANN BENEDIKT DIPL PHYS ;SPITZL RALF DR DIPL PHYS (DE)) 17 July 1997 see column 3, line 14 - column 4, line 11; figures</p> <p>---</p> <p>-/-</p>	1,2,8

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

\* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search

16 December 1998

Date of mailing of the international search report

28/12/1998

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
